

[Backend \(Cloud\)](#)

Lovable Cloud

 Copy page

Lovable hosts your app and includes a built-in backend (Cloud) with database, authentication, storage, edge functions, and AI, no infrastructure setup required.

Lovable [hosts your app](#) and includes a built-in backend (Cloud) with a database, storage, authentication, realtime, and functions. Describe what you want directly in Lovable, and Lovable generates both the frontend and backend, ready to run. Instead of managing hardware or complex infrastructure, you get on-demand access to hosting, compute, and storage that scale automatically as your app grows.

The built-in backend utilizes Supabase's open-source foundation, which means you get a production-ready environment from day one, without needing to set up Supabase separately: a database, real-time updates, user authentication, and storage, with none of the manual setup steps. Across the docs, this is called the **built-in backend (Cloud)**, as opposed to an external backend you connect yourself, such as [Supabase](#).

Why use the built-in backend

Three things make it the default choice for most projects:

- **Scales as you grow:** From your first prototype to millions of users, Lovable scales seamlessly with your needs.
- **Secure by default:** Enterprise-grade authentication, fine-grained access controls, and compliance best practices protect your app and data.
- **Cost-effective:** Manage multiple projects in one workspace with credit-based usage. Lovable includes monthly Cloud grants on Free, Pro, and Business plans. For details, see [Credits and usage](#).

Each area has its own page with full details, in the order they appear in the Cloud view:

Area	What you can do
Emails	Send branded emails from your own domain
Database	View tables, edit records, review security policies, and restore backups
Users	Manage app users and configure sign-in methods
Storage	Create buckets and manage the files your app stores
Secrets	Store API keys and other sensitive values securely
Jobs	Review scheduled background tasks and their run history
Edge functions	Run serverless backend code and monitor how it performs
SQL editor	Run SQL queries and commands against your database
Logs	Debug errors and track backend activity
Usage	See what drives the project's run credit usage
Advanced settings	Resize the instance, export data, and pause or remove Cloud

Your app's [AI features](#) have their own **AI** section in the **More** menu, outside Cloud.

Enabling the built-in backend (Cloud)

By default, the built-in backend (Cloud) is enabled for your workspace. When a feature you ask for requires backend functionality (for example, authentication or file storage), Lovable enables Cloud automatically or asks for your approval in chat first, depending on the **Enable Cloud** permission described below.

Lovable can't turn Cloud on from inside a [draft](#). Ask in the main version of your project instead, then continue in the draft once Cloud is on.

Cloud permissions

Each Cloud tool has three permission options:

- **Always allow:** Lovable automatically performs the action, without asking for review or approval. This is the default for Cloud.
- **Ask each time:** Lovable asks for your approval whenever the action is needed.
- **Never allow:** Lovable blocks the action, informs you that Cloud access is required, and instructs you to enable Cloud.

Tool settings and defaults

Setting	Description	Default behavior
Enable Cloud	Create and connect a Cloud project to add backend features (database, auth, storage). Required to use Cloud tools.	Always allow
Where projects are hosted	Select the default region (Closest to me, Americas, Europe, or Asia Pacific) where new projects are hosted. If Cloud is auto-enabled using Always allow, this region is used automatically.	Region closest to your location
Read database	Allow Lovable to read your database.	Always allow
Read analytics	Query logs to investigate issues and behavior.	Always allow
Run security checks	Run automated security checks on your database. Not a full audit.	Always allow
Modify database	Make schema and policy changes via SQL migrations. Updates generated types.	Always allow
Add data	Add data to your database tables.	Always allow
Read project info	Read project configuration and environment details.	Always allow

You can change your Cloud tool preferences anytime: open **Connectors**, select **Cloud**, and adjust the settings under **Manage my agent's permissions**.

Region selection

Projects can be hosted in three regions:

- Americas
- Europe
- Asia Pacific

You can set a preferred default region for new Cloud projects under **Where projects are hosted** in the same permissions view. If no preferred region is set, Lovable automatically preselects the region closest to your current location, and you can change it before confirming.

Choosing a region closer to your users results in:

- Lower latency
- Faster database responses
- Region-based data hosting
- Better overall backend performance

ⓘ After Cloud is enabled, you cannot change the selected region, and you cannot move existing projects between regions.

To see which region an existing project is hosted in, go to **More** → **Cloud** → **Overview** → **Advanced settings** → **General** → **Project location**.

different region when creating a project. The setting applies only to new projects. Existing projects keep the region they were created in.

Country-specific regions (for example, Germany, Japan, or United States East) are available on Enterprise plans by request. Contact your Lovable account team to enable them for your workspace.

See [Default hosting region](#) for more information.

Tutorial: build a CRM by prompting

This walkthrough builds a real app, a customer relationship manager (CRM), entirely by prompting. Each step introduces one backend capability and shows the kind of prompt that activates it.

Build me a CRM tool to manage clients, track deals, handle invoices, and keep notes organized. Keep the design simple, modern, and business-friendly with a sidebar for navigation.

Step 1: Organize the data (Database)

Tell Lovable what kind of information the tool should keep track of for you. Lovable will automatically create the tables for you, so you don't need to touch databases yourself.

I want a place to keep track of my clients with their name, email, phone number, and notes. I also need a way to track deals, including which client it's for, the value, the stage it's in, and when I expect it to close. And I need a section for invoices with the client it belongs to, the amount, the status, and the due date.

add a login to the app. Require login before accessing the CRM dashboard. Also, add a 'Sign in with Google' button so users can log in with their Google accounts.

Step 3: Handle files (Storage)

You can let users upload and see files right inside the app. Lovable takes care of the storage and linking, so you just describe what files should go where.

Add a contract upload field to each deal. Let clients have profile pictures and display them on the client detail page. Upload invoice PDFs and show a download link on the invoices table.

Step 4: Automate workflows (Edge Functions and Jobs)

Set up automatic actions that save you time. Prompt one automation at a time so each one is set up and tested properly:

When a new lead is added to the Clients table, send me an email notification.

Analyze client meeting notes with Lovable AI and save a sentiment score in the Clients table.

Schedule a daily job at 7 AM that emails me a summary of today's follow-ups.

When a payment is marked 'paid' in Stripe, automatically update the related invoice's status to 'Paid'.

Step 5: Connect to other tools (Secrets)

Services like Stripe or Resend give you private API keys. Lovable prompts you to add them securely whenever they're needed, and only your app can use them. Tools that sign in with an account instead of a key, such as Google services, connect through [Connectors](#).

Connect Stripe so clients can pay invoices online. Ask me for any API keys you need.

Step 6: Add AI superpowers (AI)

Make the tool act like your assistant.

Summarize each client's meeting notes and save them to their profile. Suggest next steps for every open deal. Generate personalized email drafts for following up with leads. Classify client messages into categories: sales, support, or billing.

Cloud and AI gateway usage costs

Lovable uses one credit balance for building your app, hosting it and running its built-in backend (Cloud), and AI features in deployed apps. Cloud and AI gateway usage is measured as part of **Run credits**.

See [Project usage](#) for the per-project usage breakdown and monthly grants, and [Credits and usage](#) for how credits work across your workspace.

FAQ

- ▶ Can I remix Cloud projects?
- ▶ Can I migrate my project from Supabase to Cloud?
- ▶ Can I migrate my project from Cloud to my own Supabase?
- ▶ Can I set a default region for all new projects?
- ▶ How is the region selected when I enable Cloud?
- ▶ Can I change the region after enabling Cloud for a project?
